AI usage details | QuantumX AEGIS

Disclosure date: 26 October 2026. This document identifies material AI assistance and separates executed automated checks from the independent human investment review that is still pending.

Tool and role

OpenAI Codex assisted this project in the development conversation. The host's exact underlying model identifier has not been independently verified. Ordinary execution tools included Python numerical libraries, ReportLab/pypdf/Poppler, Java and Android SDK build tools/emulator, Git/GitHub and browser automation.

Component	Material AI assistance
Quantitative research	Requirements interpretation; proposed constraints; portfolio/risk/EVT/backtest/stress implementation; numerical tests; interpretation and evidence-based draft recommendation.
Website	Streamlit interface, responsive styling, selected-portfolio consistency, SQL integration, free hosting setup, logo integration, loading transition and local conversational guide.
Native Android	Java calculation engine, native mobile views/charts, local saved profiles, offline what-if/backtesting, guide, signing/build scripts and automated reference/runtime checks.
Documents	Technical report, investment tear sheet, committee memorandum, pitch materials, sources/governance records and this AI disclosure.
User contribution	The logo was supplied by the user and preserved as provided. Requirements and requested changes came from the user. No completed independent human investment validation has been recorded.

AI is not running as the portfolio decision maker

The website and native app require no external LLM key or paid inference. Both guide chats use deterministic intent rules and actual selected context. They provide navigation and explanations, cannot place trades, and do not invent market facts or record human approval. The statistical risk models are not trained generative AI systems.

Validation, privacy and human responsibility

What was checked

The assistant executed independent mathematical references, chronological leakage/window checks, input validation, application interactions, document rendering and deployment checks where recorded in Testing_and_Validation.md. The separate native engine passed 222 comparisons against Python outputs, including real rolling validation. Completed emulator checks are recorded in mobile_runtime_checks.json.

Failures were retained and repaired in code or test fixtures, not concealed by editing financial output. The original portfolio still receives REVISE because training/crisis/scenario losses breach proposed limits. Native and website numerical assessments never imply a completed human sign-off.

Chat handling and application scope

Website chat text is processed by the Streamlit hosting server and retained by the app only in the current session; it is not sent to an external generative AI provider. Native guide text and saved allocations remain on the device; the APK requests no internet permission. Hosting/provider metadata logging is outside a promise of app-level chat persistence.

The native app uses verified bundled data through 2026-09-30. It is an independent offline companion with explicitly limited model scope, not a live price terminal or a website wrapper. Public source contains no live credentials; private APK signing material is excluded.

Required independent human review - PENDING

Named team reviewers must inspect and substantiate the code, data provenance, financial formulas, portfolio constraints, uncertainty, stress conclusions, spending assumptions and final investment recommendation. They must be able to defend these conclusions themselves under the competition's AI-assistance rules. Agent-performed checks do not satisfy or substitute for that review.

Review record	Status
Independent reviewer name/date	Not recorded
Financial assumptions and findings approved	Pending
Final human investment decision	Pending
AI detector/plagiarism database clearance	Not performed or claimed
